providing opportunities for unrealized biostimulant potential beyond crop growth and development. This review aims to identify the predominant types of crop biostimulants, the known understandings of their modes of action, and examples of their current field efficacy with an outlook for their future.

The focus on fertilizer recovery potential is currently the leading research strategy for biostimulant use in row crop systems, with growing attention to increasing grain yield, which is often a result of more efficient nutrient use. While many biostimulants are targeted for application to row crops for increased productivity, many products achieve these responses through impacts on soils and the biology of the root zone. A closer evaluation of biostimulant effects on soil quality and biological indicators may reveal previously unknown benefits to application. With their greater government and public awareness of agronomic practices and their influence water quality and nutrient management, the use of biostimulants as a solution to more sustainable practices and improved soil quality provides a viable option even in the absence of measurable yield increases. Grain yield due to seaweed bio-stimulants application varied from 5.31 to 5.58 t/ha and significantly increased over recommended dose of fertilizer alone (5%). Percent increase of grain yield was 4.15 to 9.14 per cent over recommended dose of fertilizer (Arun et al 2020).

The experiment was conducted to study the effect of bio-stimulant YIELDON on the yield and yield attributes of transplanted rice in kharif 2021-22seasons 2021 and rabi randomised block design with nine replications. The YIELDON was applied as foliar spray three times at tillering, panicle initiation and booting stage. The vield attributes and vield was significantly superior in YIELDON treated plots over control.

The average percentage grain yield increase was 12.04 % in T3: Yieldon

|  | 1.5L/ha followed by 11.15 % in T4:<br>Yieldon 2L/ha and 10.97 % in T2:<br>Yieldon 1L/ha treatments over control<br>treatment. |

## a. Objective

• To evaluate and test effect bio-stimulant YIELDON on crop growth, physiological and biochemical changes, and yield of Rice crop

# b. **Methodology**

The experiment was conducted to study the effect of bio-stimulant Yieldon on the yield and yield attributes of transplanted rice in kharif 2021 and rabi 2021-22seasons in randomised block design with nine replications. The yYeldon was applied as foliar spray three times at tillering, panicle initiation and booting stage.

#### c. Yield attributers & Yield

Plant height was recorded at 30, 60, 90 days after transplanting and at harvest time and there was no significant difference among four treatments AT 30, 60 & 90 DAT. Number of tillers per square meter varies at critical stage of growth. Yieldon treatments influenced the number of tillers per square meter significantly at all stages of growth. Maximum no of tillers was recorded in T4: Yieldon 2L/ha (604) followed by T3: Yieldon 1.5 L/ha (523) and T2: Yieldon 1L/ha (423) which contributed for higher yields in treated plots whereas lower no tillers per square meter was recorded in untreated control plot (382).

The chlorophyll content in plant leaves was recorded by SPAD meter at 30, 60 and 90 DAT and were not significant at all stages. Maximum SPAD readings were recorded in Yieldon treated plots over control. The maximum SPAD value content indicates the higher chlorophyll and photo synthesis.

The mean no of panicles per square meter was significantly higher in Yieldon treated plots over control. The mean maximum panicle no per square meter was recorded in T4: Yieldon 2L/ha (592) followed by T3: Yieldon 1.5L/ha (514) followed by T2: Yieldon 1L/ha (420). The Yieldon treatments contributed significantly for higher panicle weight and no of grains per panicle over control plot. Yieldon treatments did not contribute significantly for test weight.

Treatment with Yieldon was significantly contributed for higher grain yield over control plot. Maximum grain yield was recorded in T3: Yieldon 1.5L/ha (6.61 t/ha) followed by T4: Yieldon 2L/ha (6.56 t/ha) and was on par with T2: Yieldon 1.5L/ha (6.55 t/ha) whereas the Control treatment recorded 5.90 t/ha.

The average percentage grain yield increase was 12.04 % in T3: Yieldon 1.5L/ha followed by 11.15 % in T4: Yieldon 2L/ha and 10.97 % in T2: Yieldon 1L/ha treatments over control treatment.

The mean average straw yield recorded was 7.24, 7.22 and 7.16 t/ha in T3: Yieldon 1.5L/ha, T2: Yieldon 1L/ha and T4: Yieldon 2L/ha treatments respectively. The treatments contributed significantly for straw yield. The trend is nearly similar in terms of harvest index values in Yieldon treated plots which contributed for higher yield.

# d. Saving of water, labour, time and energy

Net energy output was more in Yieldon treatments and Energy productivity was more in Yieldon treated plots (0.80, 0.79 & 0.78 kg grain / MJ input energy in T3, T4 & T2) over control (0.71 kg grain/MJ energy) plots.

# **Phytotoxicity**

Phytotoxicity data was collected before the spay and 5, 10,15 days after spraying. There was no phyto toxicity by abiotic stress symptoms were observed across the Yieldon treatments.

## e. Cost effectiveness including B:C ratio

Cost of cultivation was nearly same in all treated and control plots but the benefit cost ratio was superior in Yieldon treated plots and higher B:C ratio was recorded in Yieldon 1.5 L/ha followed by 2.0L/ha and 1.0 L /ha(1.93, 1.91 & 1.82) over control (1.64).

# f. Passport data of the product/ technology

The focus on fertilizer recovery potential is currently the leading research strategy for biostimulant use in row crop systems, with growing attention to increasing grain yield, which is often a result of more efficient nutrient use. While many biostimulants are targeted for application to row crops for increased productivity, many products achieve these responses through impacts on soils and the biology of the root zone. A closer evaluation of biostimulant effects on soil quality and biological indicators may reveal previously unknown benefits to their application. With greater government and public awareness of agronomic practices and their influence on water quality and nutrient management, the use of biostimulants as a solution to more sustainable practices and improved soil quality provides a viable option even in the absence of measurable yield increases. Grain yield due to seaweed bio-stimulants application varied from 5.31 to 5.58 t/ha and significantly increased over recommended dose of fertilizer alone (5%). Percent increase of grain yield was 4.15 to 9.14 per cent over recommended dose of fertilizer (Arun et al 2020). The experiment was conducted to study the effect of biostimulant YIELDON on the yield and yield attributes of transplanted rice.

12. Details of relevant data generated during the development/validation

Table. Phytotoxicity by abiotic stress in rice as influenced by application of YIELDON (0-9 scale)

| Treatement |          | Γ      | Days after application |    |    |    |  |  |  |
|------------|----------|--------|------------------------|----|----|----|--|--|--|

| 13. Proposed stakeholders        | Transplanted rice farmers |
|----------------------------------|---------------------------|
| 14. Commercial potential, if any | Can be commercialized     |
| 15. Publications/photos/video    |                           |
| clipping, if any                 |                           |

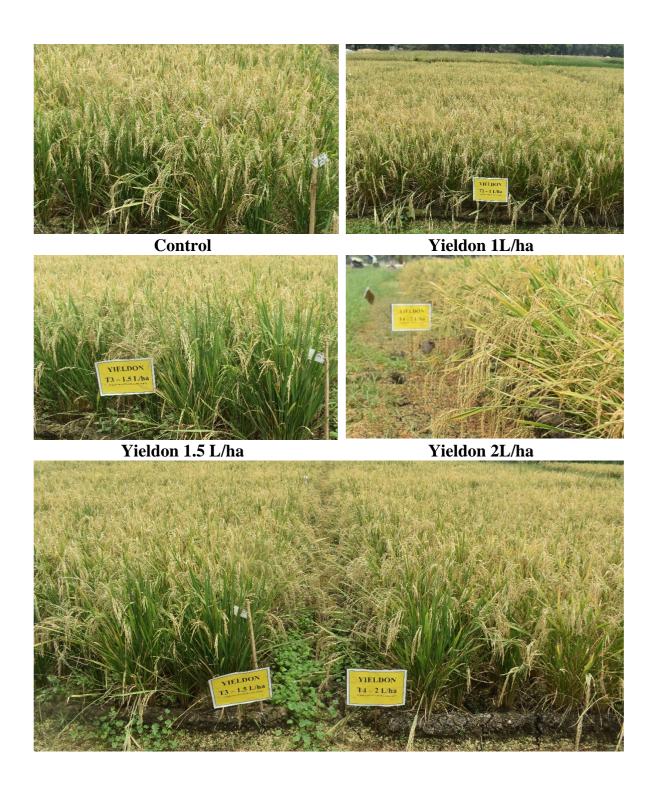

Plate 1. YIELDON experimental plot at harvest stage

- Use of Yieldon product significantly enhanced the growth parameters and grain yield
- Among the treatments T4 (Yieldon 2L/ha) found superior with 12.04% followed by T3 (Yieldon 1.5L/ha) 11.15 % and T2: (Yieldon 1.5L/ha) 10.97 % grain yield increase over control and found promising in terms of grain yield.
